## Explanation:-

Here, instead of using 'self' what I will do is, I will create another 'python' file which is `Test2.py`

Same code copy paste here & instead of using 'self' I will use my name.  
"such": 1:16/00

- \* If we execute it, as a outcome we can see over here. Its working as it is.
- \* Note:- whatever 1st variable that we are going to take that will behave as a pointer for any function that we are going to write.
- \* we are writing a function, but we are writing end of number of parameters as requirement of the function, itself.

But, here we have to write additional parameters that will behave as a pointer.  
that will point toward a class at any point of a time.

\* `_init_` what is the meaning  
of `init`.?  
with the help of `init`, we are just  
try to pass a data. so that If I have  
to do something.

## Code

\* class person :

def \_\_init\_\_(self, name, surname, emailId,  
year\_of\_birth):

Sudh.name1 = name

Sudh.surname = surname

" "

ans1 - var = person ("anuj", "bhandari",  
1994)

Sudh. = person (" ", " ") , , . 1994 )

gargi = person ("gargi", "xyz",

print(Sudh.name1 + Sudh.surname) ✓

print(ans1.var.name1)

print(Sudh.name1)

print(gargi.name1)

print(type(Sudh))

(right click)  
run code  
test2

test2 |

C:\users\win10\anmol91

Sudhanshu · kumar ✓

anuj

Sudhanshu

gargi

let's understand

Question :-

Can you please try to give me a concatenation of 'Name' and 'Surname' for 'Sudhanshu' for 'sudh' variable.

Can you please try to give me a concatenation of name and ~~ss~~ surname.

To this first of all, I have to access the data, once I will be able to access the data, then I will be able to do a concatenation.

Now, I will be able to access 'Sudhanshu' 'name' and 'surname'.

If we run this code, as a outcome we can see below - Print(sudh.name1+sudh.surname)

Sudhanshu Kumar  
Anuj

Sudhanshu  
Gargi

How I got this outcome, simple or how I can access.

\* ~~variable~~ Sudh. name1 + Sudh. Surname  
variable variable

These line code, I am able to do my concatenation operation. Obviously, it should be a string (str).

1st thing is access a data.

\* Note :- Just for understanding

S = "Sudhangshu"

S1 = "Kumar"

print(S+S1)

outcome → "Sudhangshu Kumar"

V = "Vijay"

V1 = "gurung"

print(V+V1)

→ "Vijaygurung"

So, when we write a simple thing.

$s = "Sudhangshu"$

$s1 = " Kumar"$

print ( $s+s1$ )

~~As a~~ we have created basically variable  
of a string (str) class. - 's'  
variable class of string - 's1'.

Then, If we try to call both the variable  
then we will be able to get.  
'Sudhangshu Kumar'

---

Similar way, exactly we are trying to  
do same thing over here.

Someone has already written a 'class'

and 'object.'

This is the only reason we are able

to create it.

But here in code, I am talking about  
my own custom instances. own custom 'class'

custom 'variable', I am trying to create

I am not talking about 'inbuilt' one.

## Code

class person:

```
def __init__(self, name, surname, email_id):  
    self.name = name  
    self.surname = surname
```

self.name = name

self.surname = surname

self.year\_of\_birth = year\_of\_birth

def age(self, current\_year):  
 return current\_year - self.year\_of\_birth

year - self

anuj\_var = person("Anuj", "")

Sudh = person("Sudhanshu", "Kumar")

gargi = person("Gargi", "xyz")

↓ Substitution  
Sign (-)  
Negative (-)

Sudh.age(2022)

use this  
print(sudh.age(2022))

test 2

C:\users\192.168.1.10

-21402 ✓

Let's understand:-

Now, there is a possibility that, I would like to create a generic function. To do something, may try to calculate age of the particular person.

May I would like to create a function and with the help of that, I will be able to calculate age of person.

Requirement

Requirement:- Try to create age of a person.

So, here, I will try to create a age my own custom function.

Whenever, we try to create any function inside a class a very first variable will notify as a 'pointer.'

It is try to mention these entire this to the 'classes.'

To calculate age, I need what To calculate particular age, I need basically a 'current year' & 'year of birth'

If I am going to do a subtraction difference of it, it will give me a 'age'.

```
*def age(sudh, current_year):  
    return current_year - sudh.year_of_birth
```

Can we say 'Year of Birth' any how we are going to pass. at the time of creation of variable of the classes.

Any how 'Year of Birth' we will going to pass.

That will be ~~available~~ available inside a class, class is aware about 'Year of Birth' for these particular person. any how by default.

If I have to call class variable how, I will be able to ~~call~~ call a class variable.

Here also same changes made

def age (self, current year; )

return current year - self.year - birth

my pointer self, we changed it as 'such'.  
by default but

my pointer 'self' by default, but I changed  
it made 'such'. So, pointer such.year - birth.

So, now these 2 one code function,  
I have written inside 'class'

class person:

the only difference between a function  
that, we are writing so far so forth is  
these function on pointers (self or such)  
helping me out to call any thing  
from a "classes" & point anything to a  
class. This is only thing these pointer does.

\* Because, I need some reference or something, which will be allocate something to my classes.

So, these current year & ~~year~~ year of birth class, which I have created I am trying to pass a data by creating a variable. So at the time of creation of variable.

I am going to pass a data there is a function.

Now, anything that we have to called from the class whether it's a variable that we are able to call or it's a function that I would like to access. Now, I will be access, can I say that I will be access it with the help of 'class variable' or 'objects'; I will be able to call it.

But, how I will be able to access  
name.

Can, I say that (Anuj\_var.name1)  
(variable.name1)  
" : surname  
" : year-of-birth.  
etc.

This is how, I am able to call it.  
similar way,

If we have to call even a function  
how we will be able to call a function.

Let's suppose,

I am trying to call 'Age' ?  
Age for whom we would like to call.  
for \*Anuj,  
\*Sudhanshu or  
\*gargi

24:35

For which person, would like to get or  
understand the 'Age' ?

I can get the Age for all three(3) or  
get a Age for anyone.

- \* ① Anuj-var = person ("anuj", "bhandari", "", "")
  - ② Sudh = person ("Sudhanshu", "kumar", "", "")
  - ③ gauri = person ("gauri", "xyz", "", "")
- ~~Sudh.age(2022)~~
- ~~print(Sudh.age(2022)) or print(sudh.age(2022))~~
- test2.py
- C:\Users\HP
- Just for understanding*

-21402

use this  
code &

Run the code &  
test2 right click

Now, here, I have to call a as 'Age',  
let's suppose for 'Sudh' we would like to  
call a 'Age'  
what we will do.

Sudh.age  
↓  
variable

so, 'Age' wise looking for a parameter, it is  
asking that, can you please try to provide  
current year.

So the current year is what it's a  
~~2022~~ that I am going to pass.

Now once we are going to call these  
function.  
It is going to pass current year is  
2022.

(Sudh.age(2022)) will get from where.  
From here, it ~~will~~ get that.

\* def .age(sudh, current\_year):  
    return .current\_year - sudh.year\_of\_birth

Because, anyhow, I am trying to pass  
year-of-birth. whatever **class variable** if I have  
to call within our class, I have to use  
a pointer. whatever name of a pointer will  
be going to define, by default we will be  
able to find out. 'self' everywhere.

If we execute this code, As a outcome  
we can see, I am able to get the  
result.

outcome - -21402 ✓

Code

\* class person:

def \_\_init\_\_(self, "name", "age")

"

"

def age(self, current\_year):

"

Anuj-var = person(

Sudh = person

Gargi = person

print(Sudh.age(2022)) ~~x~~ → print(Anuj-var.age(2022))

~~print(Anuj-var)~~

Now change here. 'Sudh'  
make it 'Anuj' then we  
will get Anuj's Age.

test 2

---

C:\Users\1win90

28 ✓

## Let's understand

Here,

Let's suppose, I want to know the age of 'Anuj'.

So, below I will make change.

\* anuj-var = person("anuj", "

Sudh.= person ("Sudhanshu", "....")

gargi = person ("gargi", "xyz", "....")

print(anuj-var.age(2022))

Test:  
Courses

28

So, here in the last line code, we made change is that, from.

\* print(sudh.age(2022)) TO

\* print(anuj-var.age(2022)) ✓

So, that is why we get the age of 'Anuj'.

So, it is trying to do what.

It is trying to pass a  
'current year' values over here.

\* def age(suoh, current\_year):

return current\_year - suoh.year -  
birth

Then it is trying to ~~subtract~~

Subtract (-) Age or year of birth that  
I have passed.

\* return current\_year - suoh.year -  
birth

This is symbol of (-)  
Subtraction & here I am  
doing subtraction.

Here, what I am saying is,

How I am able to access

'Age'.

I am able to Access 'Age' with the  
help of these 'class variable.'

Note:-

For understanding only - Example :-

let's suppose I have created

$s = "such"$

Can you please convert this into a 'Upper' case.

we will call  $s.upper()$

~~dot(.) upper()~~

$s = "such"$

$s.upper()$

This method we have already done,

~~This is what we do.~~

we trying to do, is, we have declared a class variable of a "String" then from that class. string class, with the help of that variable we are trying to call a function. This is we have learn in our 'String' class. Similar way for others also.

'list'

'integer'

'tuple'

, dictionary, set etc.

For all these must be some function  
which is available.  
Here also we have done same  
thing.

$$\text{“Abn2”} = 0$$

(Required)

Code

Code

class person:

def \_\_init\_\_(self, name, surname,  
              self.name1 = name, " ", " ", ):

    self.surname = surname

" "

    " "  
    self.year\_of\_birth = year\_of\_birth

def age(self, current\_year):

    return current\_year - self.year\_of\_birth

anuj\_var = person("anuj", "bhandari")

Sudh = person("Sudhanshu", "Kumar", "Sudhanshu@Gmail.com")

gargi = person("gargi", "xyz", "123424")

print(anuj\_var.age(2022))

test 2:-

\* Error outcome

Traceback: /usr/bin/python3 -

anuj\_var = person("anuj", "bhandari")

TypeError: \_\_init\_\_() missing 2 required

positional arguments: 'name' & 'year\_of\_birth'

let's understand:

let's suppose, we are going to pass maybe or it is looking for 4 inputs.

I am going to pass may be 5 or 2 or 3 what will happen that case, what happened. In term of function. It will give an Error; it will complain, you told that you will going to 2 variable, but you have passed 3 or 1.

Again it is an function, I have written. `def'`

~~def~~ - init - (

Def keyword been used for function declaration.

Although, I am using a inbuilt function over here. I am trying to over write it.

But still its a function.

what change, we made here is

In this line code we made change

\* anuj-var = person ("anuj", "bhandari",  
"anuj@gmail.com", 1994)

To

\* anuj-var = person ("anuj", "bhandari")

So, I have passed less data, name & title only  
as outcome, If we execute this code.  
It will complain or Error.

test 2:-

ocell windowsto

Roll "ccf /users -

anuj-var = person ("anuj", "bhandari")

TYPE Errors: -- init - 1) missing 2 required  
positional arguments: 'emailId' &  
"year-of-birth"

missing & requirement.

we have missed that you told me  
you will provide Email ID & date of birth  
you have not provided.

So, as a outcome it Complaining that  
Email ID & date of birth  
2 things missing, which is

\* So, whenever we are trying to pass a  
data so, yes as per the function  
declaration, we are suppose to pass  
a data.

Code

class person:

```
def __init__(self, name, "
```

Sudh. name1 = name

Sidh. Surname = Surname

~~Sudh. emailID = emailId~~

~~SuCh. emailID = email~~  
~~SuCh. year\_of\_birth = year\_of\_birth~~

def age(such, current\_year):

return current year - such year of birth

ənūj-var = person ("ənūj," "bhāndar," "ənūj@gmail.com"  
1994)

Sudh.= person ("Sudhangshu", "Kumar", "Sudhangsh@gmail.com",

*Jorgi* = person( , 23424) ; . . . 234242)

```
print(annu$var.age(2022))
```

test 2:  
c:// wendao 10

outcome same

## Let's understand :-

Let's suppose,

Here, I am going to remove a 1 variable from these out of total 4 variables.

\* `def __init__(self, name, ...):`

① `self.name1 = name`

② `self.surname = surname`

③ `self.emailId = emailId`

④ `self.year_of_birth = year_of_birth X`

If I remove out of these 4 variable last one remove and only use above 3 variables  
Is it going to work?

\* `def __init__(self, name, ...):`

① `self.name1 = name`

② `self.surname = surname`

③ `self.emailId = emailId`

Rest below code don't change anything.

As a outcome, it will not complain anything, its completely fine, we will get ~~our~~ our outcome.  
Simple, instead of ~~4 variable~~, I am only using ~~3 variables~~ that is fine.  
~~My outcome will same.~~

Opps

2nd one.

2nd option (~~--init--~~)

It is just trying to over right the  
1st one 1st (~~--init--~~).

Next code line code correct one <sup>next page</sup>  
~~same~~  
Continue...

## Code

oops  
project

main.py | test.1 | test.2 | test.3  
class person:

def \_\_init\_\_(self, name, "  
" year-of-birth):

1 Sudh.name1 = name  
2 "  
3 "  
4 "

def \_\_init\_\_(self, name, surname):

Sudh.name1 = name

Sudh.surname = surname

def age(Sudh, current\_year):

return current\_year

anuj\_var = person("anuj", "shandari")

Sudh = person("Sudhanshu", "kumar")

gargi = person("gargi", "xyz")

print(anuj\_var.age(2022))

test3.py  
C:\Users\win10\

2022 outcome.

let's understand it

Here,

'In these code, we have made a lot of changes.  
what change, we have made over here.  
we have removed.

\* 1st return current - year Sudh.year-of-birth  
Now,  
return.current - year. X Remove it  
Because there is no year of birth so.

\* 2nd  
\* anuj-var = person("anuj", "ghandari")  
Sudh = person("sudhangshu", "kumar")  
gargi = person("gargi", "xyz")  
print(anuj.var.age(2022)) (Here we have removed, year of years)  
Note: we have remove 2 places 2 things.

1st place only these one

Sudh.year-of-birth.

2nd place we have removed. 1 year & 2 years..

Now only Name & Titles.

Now, AS a outcome we can see that, we are getting.

It is taking 2nd option or 2nd (-init-).

Note :-

If we are going to write multiple -(-init-). means 'multiple constructor' to pass a data.

It is always going to take ~~last~~ last one or latest one.

Both are same.

Again, it is not mandatory ~~to~~ to pass a data.

may be I have just created a 'class' end up writing a couple of methods couple of function over there. without passing a data to my classes. that is completely fine.

\* But, If we would like to pass data at time of creation of an object, only in that case (init) is required.

dob = input("tell me your date of birth")  
return dob

Sudh = person()

Anuj = person()

Gargi = person()

Krish = person()

Hitesh = person()

Note:

This is Half  
Code don't run it  
next page actual  
explain what we expect  
information we are looking.

let's understand

test4.py

Here, I have created "class person".  
Inside that, I am not going to create  
any kind of \_\_init\_\_.

\* def age(self, ):  
 return current\_year - year\_of\_birth

so, I have created a class inside that,  
I have created one function.

\* I can create another function, I would like  
to take input from the email ID.

def email\_id\_input( ):  
 print("Enter your email ID: ")

\* Now, another, I can write a function

def ask\_name(self):  
 ""

\* Now, here again another function,  
user input, Input is a function.

\* def ask\_dob(self): — dob (date of  
birth)  
    "  
    "  
    ";

So! Here in code, I have just created a  
'person class':

I have to take some sort of a  
input from a 'user' or may be from  
calculation, I have to do for all the  
"users." whoever 'user' who is going to  
register with me. I just have to ask to all  
the users.

\* I have not created any (- - init - -)  
Over here, I am not looking for any kind of  
input from user at the time of creation  
of variable.

Now, how I will be able to create a variable for a particular person.

\* Sudh =

\* anuj =

\* garge =

\* Krish =

\* fltresh =

let's suppose,

I have a person, 5 person over here.

\* Sudh

\* anuj

\* garge

\* Krish

\* fltresh

I have to take a input, or

Question :-

- ① Can you please tell me ~~fltresh~~ email ID?
- ② Can you please " .. Krish date of birth?
- ③ Can you ~~tell me~~ please " .. Sudh age or something?

So, these are few questions, if some one going to ask.

Otherwise, I have so many users. If I have to take there inputs & everything depend upon my context, which I am looking for.

So, ~~first~~ first of all I have to declare a variables, a class variable.

I have to call age or some time email ID, date of birth, these are thing which I am suppose to call.

Here, we are not using any '`init`'.

So, whatever function, we are going to create, we have to take 1st parameter by default, we can use '`self`' or we can use own name ~~or~~ anything.

- \* 'self' is not a reserved keyword inside python, just for reference, we can use any keyword.

\* such = person()  
\* amit = person()  
\* gauri = person()  
\* Krish = person()  
\* Hitesh = person()

Here, I have to have to created variable of what "person class".

such = person() variable creation done.  
Is our class looking for some input at the time of variable creation. This time?

No, right.

But, in our previous class we have created a constructor.  
Responsibility of constructor is a one again method by default.

\* Responsibility of 'constructor' is to take a input from the user.

But, here, in this code, I have not created anything like that.

Such = person()

"

"

"

Hitesh = person()

So, 'Such' become 'person variable' like for all anu . . . . Hitesh.

Now, variable of these person class I have created.

By time I am going to create these variable, can I say that, now all the function which I have written inside these class will be accessible by all the variables.

\*  $s = \text{'Such}'$   
 $s. \text{upper}()$

let's suppose,

this is my string (str).  
variable which I have created over here.

Can we say, now this variable will  
be able to access all the method of  
string (str).

whoever has written any method  
with respect to string for that libraries.  
They will be able to access each &  
all  
every thing.

\* So, the "Such" is a variable of person  
technically its a object.

"Such"

"ani"

"

"Hitesh"

Everyone become an object.

variable of person classes.

If its a variable of person classes.

So, the way we are access all the str.

String method, by using a string variable  
similar way.

we will be able to access all  
the method of these class by using  
these variable.

```
def age(self, " "
"
"
"
def - ask_job(self):
    "
    "
```

## Code

OOPS

prosefs

OOPS

main.py

test1.py

test2.py

test3.py

test4.py

main.py | test1 | test2 | test3 | test4

~~class per~~

~~class person:~~

```
def age(self, current_year, year-  
g-birth):  
    return .....
```

```
def email_id_input(self, email_id):  
    "
```

"

```
def ask_name(self):  
    "
```

"

```
def ask_dob(self):  
    "
```

"

```
return dob
```

Sudh = person()

Anu = person()

Gargi = person()

Krish = person()

Amitesh = person()

✓ Sudh.email\_id\_input("Sudhanshu@neuron.ai") ①  
- print(Sudh.ask\_name()) ②

Test 4

C:\Users\win10

Take and email id from a person & print it

→ Sudhanshu@neuron.ai

Tell me your name

Sudhanshu Kumar

4  
5

Let's understand :-

Now

'Some one asked me question,  
Can you please tell me "email ID" of  
a person → 'Sudh'?

So, simple, I will do.

I will add one line code in ~~for~~ for  
these. ~~(A)~~

(A) \* Sudh.email\_id = input("sudhanshu@ineuron.ai")

If we execute these code as a outcome  
we can see.

C:\Users\prin20

take it mail id from a person ...

\* sudhanshu@ineuron.ai ✓ outcome

Email Id we are able to get.

2nd part (B)

Question :-

Some one asking Can you please  
asked a name a full name of 'Sudh' ?

1:41:20

Yes,

- \* Sudh\_email\_id\_input ("sudhanshu@newton.ai")
- \* Sudh\_email\_id\_input ("sudhanshu@newton.ai")
- \* Sudh.ask\_name()

If we execute by putting this one line  
piece of code. ~~print "Hello"~~

As a outcome we can see.

test.py/  
C:\Users\window10

take and mail id form a person & print it

Sudhanshu@newton.ai

tell me your name

Sudhan shu Kumar

## Code

main.py / test1 / test2 / test3 / test4

Class person :

```
def age(self, current_year, ...)  
    return ...
```

```
def email_id_input(self, ...)  
    ...  
    ...
```

```
def ask_name(self):  
    ...
```

```
def ask_dob(self):  
    ...
```

```
    return dob
```

sudh = person()

anuj = person()

...  
...

hitesh = person()

```
sudh.email_id_input("Sudhanshu@ineuron.ai")  
print(sudh.ask_name())
```

~~print(hitesh.ask\_dob())~~

C:\Users\win10

tell & mail to form a ... Sudhanshu@ineuron.ai  
tell me your name . 'Sudhanshu Kumar'  
Sudhanshu Kumar  
tell me your date of birth 3453453  
3453453

Dear Mr. C.  
Date 27/10/2023

Let's understand

Q: Now someone is looking for Date-of-Birth.  
ASK Date-of-Birth of "Hitesh".

\* print(hitesh.ask\_dob())

outcome → 3453453 (I can give like this also)  
27 10 1995.

In that case what I will do, I will call  
first 'Hitesh' variable.

Because all of them are able to access all  
the ~~for~~ 4 variables or the 4 methods.  
ask Date of Birth; If by putting this  
number as Date of Birth print it.

print(hitesh.ask\_dob())

```
* Sudh. email_id - input ("Sudhanshu@ineuron.ai")
* print(Sudh.ask_name())
```

```
* print(Hitesh.ask_dob())
```

If execute .pt

Asking for name, so put  
'Sudhanshu Kumar' & then asking for  
Date of birth. 'Hitesh' date of birth  
asking from Hitesh variable.

(3453453) - we have provided over here  
3. Can put like this also - (27101995),  
this is fine.

As a outcome we can see over  
here is (3453453) I am able to get.

So, here Sir is trying to show a reusability of a code.  
I have just written 4 for 4 function inside particular classes.

\* def. age(self,  
return

\* def. email\_id\_input(self,  
print ("")

\* def. ask\_name(self):  
name =  
return

\* def. ask\_dob(self):  
dob =  
return

Let's suppose, I have 1 millions people,  
can I say that for all 1 million people  
I will be able to use all of these 4 function.  
I don't have to rewrite again &  
again. Now its become generic code.

Now, we have created these 'class' over here.  
inside these 4 function.

Now, I will just keep adding a  
function as much as possible.

~~After that person~~

Can I say that for person, I ~~can write~~  
will end up writing all kind of functions.

Every kind of function, I will end up writing.  
Now next user whoever has to use  
basically any of these function.

They don't have to write it; it's  
a ready made available they just have  
to call. and they will be able to use it.

- \* So, I am able to increase the scalability  
of a code. ~~I can do~~
- \* I am able to increase the ~~use~~ reusability  
of a code at the same point of a time,  
by using 'classes'.
- \* Difference ~~left~~ between 'class' & 'object'.

So, far so forth here we are writing a function but in a screen for now.

we have written one function one file somewhere.

~~Another~~ Another file somewhere, this is what we are doing.

Can we say that, now we have started collecting a similar kind of a function, function which belong to a person.

\* Now, if I will create another 'class' where I will write all the function related to 'Car'.

'class person' or 'class ~~cat~~ car'

this will my choice whether I will use 'person class' or 'car class'.

Just to create an structure we have adopted a ~~concept~~ oops concept.

Theory wise logically we are not writing anything.

Here what we are trying is, we trying to structure over here, so that I will be able to 'package or Bundle' a things.

So that I will be able to maintain a code, because number of One of Code Please, it hard to maintain.

\* let's Suppose,

we have written thousand One of Code & question is that can you please find out Test 4 function that we have created in our classes. It will ~~be~~ 'puzzle'.

\* what if going forward, we will keep all the 'list', ~~dictionary~~, Tuples etc every function in separate separate class.

- \* 'Tuples' released in a different 'class'.
- \* 'Dictionary' released in a different 'class'.
- \* . 'List' . . . . .

In that case, ~~we~~ can we say.  
Question is can you please call these function.

In that case, we will click  
~~'List class'~~ click & find code.  
Similar way others.

That the advantage, we will get  
if we write code these structured  
way.

### Advantage

Module

Structure

Robustness

Easy to find

Easy to develop.

Easy to implement

Because, As number of line of code will  
increase it hard to maintain so.

Q: why oops is important?

concept

If we are developing a project.

- For each person 1 task
- If one is work on 'Tuples' another is working on 'Dictionary', 'Set', 'List' etc. this way separate separate & later we combined all the code in one place or we merged all the code  
this is how project complete.

This is how we develop any kind of project & any kind of product.

This is where concept of oops come to a picture.

# TASK - Post This Class

1.57

Q:- Task 1 :- In a past whatever questions we have discussed with respect to 'list', 'tuples', 'dictionary', 'set', 'string' and try to create a separate 'class' for each and everything and restructure your code for all the segment and submit.

## Q:- Task 2:-

1: Instruction Number 1 :-

Always use exception Handling.

2: Instruction Number 2 :-

Always use logging as well.

3. Reformat your code and submit it to me before tomorrow's class.

Email ID :- sudhanshu@ineuron.ai

sunny.savita@ineuron.ai

I am only looking for your separate python file in your Github link.

All people done there task & Submitted Submitted to see those task follow below link. of (GitHub).

1. Awil padiyar :-

[https://github.com/awilpadiyar/Assignment/blob/main/oop1\\_Task.py](https://github.com/awilpadiyar/Assignment/blob/main/oop1_Task.py)

2. Rohit :-
